Abstract: Automatic multiple-choice question generation (MCQG) is a useful yet challenging task in Natural Language Processing (NLP). Examinations and Assessments are undergoing a tremendous revolution. Universities, colleges, and other educational institutes are increasingly shifting towards online examinations. The pattern of assessment is majorly shifting towards the objective assessment i.e. MCQ based, it is very hard to construct and requires a considerable amount of time for setting numerous questions. There's a growing need for a cost-effective and time-efficient automated MCQ generation system. In this paper, the text is first summarized using the BERT algorithm, and accordingly sentence mapping is done for generating MCQs. In order to generate choices for the questions, distractors are generated using wordnet (A lexical database for English). As the BERT algorithm has much better performance over other legacy methods as well as it can process a large amount of data in less time, it will enhance the speed of generating mcq's from given text.

Keywords: BERT , DISTRACTORS.

1. INTRODUCTION

All institutes, colleges, and schools have been switched to online learning. Assessment is an essential tool to test the knowledge of the students. And the pattern of the assessment has changed from subjective based to objective based i.e., Multiple Choice Questions (MCQs).

So, the problem is, it is very difficult for the teachers to set the questions as well as for the students who are preparing for competitive exams. The current method involves the setting of questions manually which requires a lot of human intervention and time. So, there is a growing need for a system that can create questions with ease and less amount of time and requires less human effort.

Automatic multiple-choice question generation (MCQG) is a useful yet challenging task in Natural Language Processing (NLP). It is the task of automatic generation of correct and relevant questions from textual data. Despite its usefulness, manually creating sizeable, meaningful and relevant questions is a time-consuming and challenging task for teachers. In this project, we present an NLP-based system for automatic MCQ generation for computer-based testing examination (CBTE). We used NLP technique to extract keywords that are important words in a given lesson material.

This project tells about a system that generates questions automatically. In Automated MCQ Generator, questions are generated automatically with the help of NLP. The text of any domain is provided as input to the system which is then summarized using the BERT algorithm. BERT (Bidirectional Encoder Representation from Transformers) is a deep learning-based technique for natural language processing, a pre-trained model from Google. Now the keywords are selected from the summarized text using the python keyword extractor (PKE) and accordingly mapping of a keyword is done with a sentence. This keyword will be one of the options of MCQ. Now the main task is generating relevant distractors. Distractors are generated using the wordnet approach. Wordnet is an API used to get the correct sense of the word. So the good and relatable distractors are generated. This system solves the problem of manual creation of questions and reduces time consumption and cost.

Natural Language Processing (NLP) is a branch of artificial intelligence that deals with the interaction between computers and humans using the natural language. The ultimate objective of NLP is to read, decipher, understand, and make sense of the written or textual data in natural languages of human in a manner that is valuable. In this paper, we focus on the setting of MCQs through NLP to improve the method of setting MCQs and modification, and for creating a viable question bank for subsequent use by the academicians for their learners. This will ensure an MCQ that includes appropriate questions and options based on the learning objectives and importance of the topics discussed in a lesson material. We used NLP methods, Term Frequency-Inverse

Document Frequency (TF-IDF) and N-grams, to extract the most significant words present in a lesson material and the selection does not depend on any vocabulary; these words are keywords that capture the main topics discussed in a lesson material, they also serve as an indication of document relevance for users in an information retrieval (IR) environment

2. DESIGN:

1.1 Requirement Specifications (S/W & H/W)

Hardware Requirements

- ✓ **System** : Processor Intel(R) Core (TM) i5-8265U CPU @ 1.60GHz, 1800 MHz, 4 Cores, 8 Logical Processors
- ✓ **RAM** : 8 GB
- ✓ **Hard Disk** : 557 GB
- ✓ **Input** : Keyboard and Mouse
- ✓ **Output** : PC

Software Requirements

- ✓ **OS** : Windows 10
- ✓ **Platform** : Google Colaboratory
- ✓ **Program Language** : Python

2.1. Flowchart

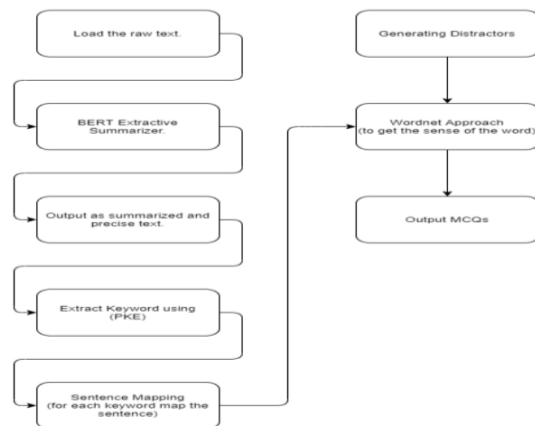

Fig 1: Flow chart representation

The text of any domain is provided as input to the system which is then summarized using the BERT algorithm. BERT (Bidirectional Encoder Representation from Transformers) is a deep learning-based technique for natural language processing, a pre-trained model. Now the keywords are selected from the summarized text using the python keyword extractor (PKE) and accordingly mapping of a keyword is done with a sentence. This keyword will be one of the options of MCQ. Distractors are generated using the wordnet approach. Wordnet is an API used to get the correct sense of the word. So, the good and reliable distractors are generated.

3. METHODOLOGY:

This section talks about the whole procedure and methods used for this project.

LOAD RAW DATA

The first step is to load raw text i.e. input text of any domain for which the questions to be generated.

SUMMARIZER

Each sentence is not capable of generating questions. Only the sentences that contain a questionable fact can act as a candidate for creating MCQs. Therefore, sentence selection plays a crucial role in the automatic MCQ generation task. Hence for summarizing the text, BERT Algorithm is used. BERT (Bidirectional Encoder Representations from Transformers) is a neural network-based technique for natural language processing. It is a pre-trained open-sourced model from Google. It helps computers to understand the language a bit more as humans do. The input text is summarized using the BERTSUM model, which is fine-tuned BERT for extractive summarization. The architecture of BERTSUM is shown in Fig-2.

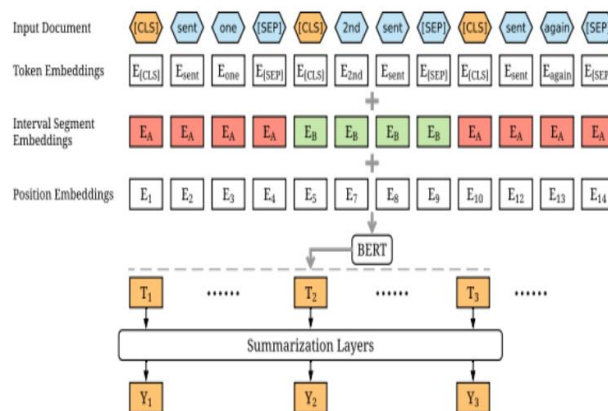

Fig.-2: Overview Architecture of BERTSUM model

KEYWORD EXTRACTION

After summarizing the text, keywords are selected from the sentence. This keyword will be the answer to the question. Since all the words in an informative sentence cannot serve as the key proper keyword selection is required. The extraction of keyword is done by python keyword extractor.

Python keyword extractor(PKE) provides an end-to-end keyphrase extraction pipeline in which each component can be easily modified or extended to develop new models.

GENERATION OF DISTRACTERS

Generating distractors is the most crucial step in the generation of automated MCQs. The difficulty of MCQs highly relies on the quality of distractors produced. A good distractor is one that is very similar to the key but not the key itself. So, for generating distractors Wordnet approach is used.

WordNet is a lexical database for the English language, which was created by Princeton, and is part of the NLTK corpus. In the WordNet network, the words are connected by linguistic relations. These linguistic relations includes hypernym, hyponym, meronym, holonym, etc. WordNet stores synonyms in the form of synsets (Nouns, verbs, adjectives and adverbs are grouped into sets of cognitive synonyms) where each word in the synset shares the same meaning. Basically, each synset is a group of synonyms. Each synset has a definition associated with it. Relations are stored between different synsets. This Lesk algorithm is based on the assumption that words in a given "neighborhood" (section of text) will tend to share a common topic. A simplified version of the Lesk algorithm compares the dictionary definition of an ambiguous word with the terms contained in its neighbourhood.

For example, if there is a sentence “The bat flew into the jungle and landed on a tree” and a keyword is “bat”, we automatically know that here we are talking about the mammal bat that has wings, not a cricket bat or baseball bat. Although we humans are good at it, the algorithms are not very good at distinguishing one from another. This is called word sense disambiguation (WSD). In the wordnet, “bat” may have several senses, one for a cricket bat, one for flying mammal etc. So the function `get_wordsense` tries to get the correct sense of the word given in the sentence. Once the sense of the word is identified the `get_distractors_wordnet` function is called to get the distractors. This function tries to get the distractors with the help of hypernyms and hyponyms of the key.

HYPERNYM:

Hypernym is a word that names a broad category that includes other words.

Ex: animal is hypernym of dog.

HYPONYM:

A word of more specific meaning than a superordinate term applicable to it.

Ex: car is a hyponym of vehicle.

Now all the possible hypernyms of the key and the corresponding hyponyms for each of the hypernym are found. These hyponyms are considered potential distractors. Then, the potential distractors are ranked, and the final distractors are chosen based on their rank. For the word 'bat' as the key, the hypernym for the bat is - an animal of which hyponyms can be an eagle and other birds which can be good distractors for the key. The ranks given to the potential distractors are based on whether it occurs in the text extracted from the summarization. The potential distractors that exist in the extracted text and having the same part of speech structure as the key have a higher rank than those with a different structure. This is because distractors with the same structure as the key tend to confuse the test takers more. Any three potential distractors with higher ranks are chosen at random as the final distractor

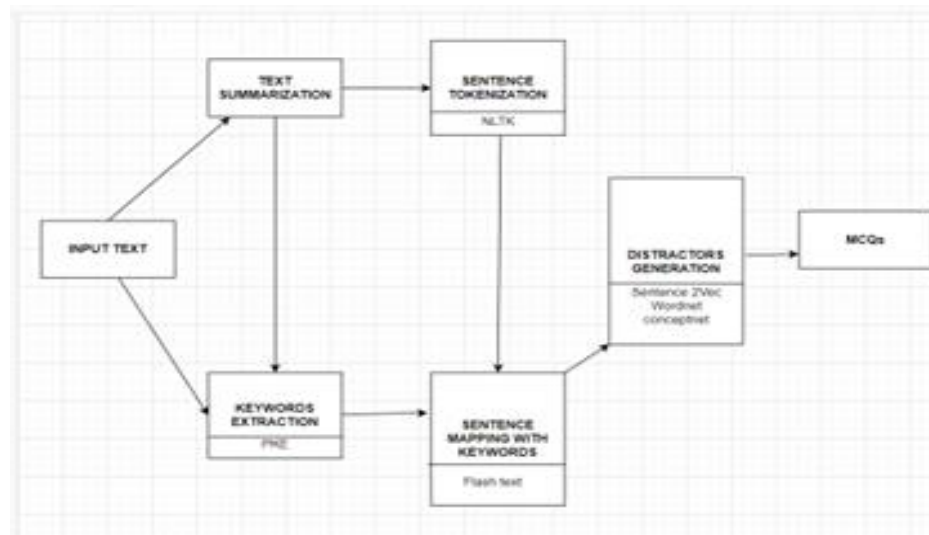

Fig 3: Process flow

4. RESULTS:

So, from the input text we are summarizing that text. From that summarized text we extracted keywords. After extracting those keywords, we will be mapping those keywords to their sentences and once the keywords are extracted, we tried to generate distractors. As we

know in the multiple-choice questions there will be correct answer in the options and also remaining options will be incorrect. Distractors are nothing but the wrong options for that particular multiple-choice question. Then the keywords are replaced with ----- . Hence becoming the question, the keyword as an answer and distractors as the other options. Finally putting all together we have generated multiple choice questions.

```

keywords.append(key)
return keywords

key=extracting_keywords(text)
print(key)
filtered_keys=[]
for keyword in key:
    if keyword.lower() in summary.lower():
        filtered_keys.append(keyword)

print (filtered_keys)

5. OUTPUT PREDICTION:

As we mentioned in the results we generated multiple choice questions with appropriate distractors.

```
Warming up PyWISD (takes ~10 secs)... took 6.916054010391235 secs.
1) _____ cut the stems into strips, pressed them, and dried them into sheets that could be rolled into scrolls.
   a ) Angolan
   b ) Egyptians
   c ) Algerian
   d ) Bantu
More options: ['Basotho', 'Beninese', 'Berber', 'Black African', 'Burundian', 'Cameroonian', 'Carthaginian', 'Chadian', 'Chewa', 'Congolese', 'Djiboutian', 'Egyptian', 'Ethiopian',

2) Because the pharaoh was thought to be a god, government and religion were not separate in ancient _____.
   a ) Iraq
   b ) Egypt
   c ) Kuwait
   d ) Saudi Arabia
More options: ['Jordan', 'Israel', 'Fertile Crescent', 'Turkey', 'Iran', 'Lebanon', 'Shari', 'Mauritania', 'Nigeria', 'Somali peninsula', 'Sierra Leone', 'Malawi', 'North Africa',

3) The _____ provided so well for Egyptians that sometimes they had surpluses, or more goods than they needed.
   a ) Buganda
   b ) Entebbe
   c ) Gulu
   d ) Nile
More options: ['Jinja', 'Lake Edward', 'Kayunga', 'gulu', 'entebbe', 'Port Sudan', 'Omdurman', 'Darfur', 'Libyan Desert', 'Kordofan', 'Khartoum', 'Nubian Desert', 'Nyala', 'Aswan Hi

4) Nubia was the Egyptian name for the area of the _____ Nile that had the richest gold mines in Africa.
   a ) Upper Berth
   b ) Lower Berth
   c ) Upper
```

Fig 6: Output result

6. CONCLUSION:

Multiple Choice Questions (MCQs) are generated successfully. Efficient questions are produced with good quality distractors. The problem of manually creating questions is solved with the proposed system. The proposed system creates automated questions with the help of NLP that reduces human intervention and it is a cost and timeeffective system. And the accuracy of the distractor generated is reasonably high. This system not only helps teachers with E-assessments but also helps students who are preparing for competitive exams. Students can test their ability to solve the questions and can also check their understanding of the concepts.
